

## ABGs

- Arteries used are radial , brachial or femoral
- Check the ulnar circulation by doing Allene's test
- Heparin is used in the tube to prevent coagulation but it may cause metabolic acidosis
- Use ice to carry the tube in to prevent further metabolism and avoid respiratory acidosis
- Air bubbles in the tube  $\uparrow$ CO<sub>2</sub> and  $\downarrow$ O<sub>2</sub> causing false reflexion of ABGs
- Jaundice and hyperlipidemia have wrong interpretation for acid – base not ventilation
- Normal range of pH 7.35 – 7.45 (7.4) , p CO<sub>2</sub> 35 – 45 (40) , HCO<sub>3</sub> 22 – 27 ( 24+/-2)
- Mixed = normal pH on the narrow range
- Partial compensation = mixed
- DKA : metabolic acidosis or mixed
- Compensation of pH moves it to upper limit of normal (7.45) or lower limit of normal (7.35) by regulating respiratory rate and tidal volume ( p CO<sub>2</sub> ) or kidneys' reabsorption of HCO<sub>3</sub>
- The ratio of p CO<sub>2</sub> and HCO<sub>3</sub> not the absolute levels determines pH
- In the case of three disorders use anion gap or base excess  
BB = buffer base : normally 48  
BE = buffer excess = normal- patient : normal range -6  $\rightarrow$  6  
If more than +6 >> hidden metabolic alkalosis despite pH and compensation
- Lungs : one disorder                      Metabolic: bone , kidney, GI
- Anion gap = Na – HCO<sub>3</sub> – Cl    Normal range 10 – 16 (12+/-4) despite pH and ABGs  
If more than 18 >> high AG hidden metabolic acidosis  
Negative urinary AG implies increased renal excretion of NH<sub>4</sub> (GI; type II RTA such as Fanconi syndrome, amyloidosis, multiple myeloma, acetazolamide; exogenous acid)  
Positive urinary AG implies failure of kidneys to excrete NH<sub>4</sub> (type I RTA, type IV RTA, early renal failure)
- Any increase in unmeasured anions always is 1:1 with the increased H<sup>+</sup>
- Compensation:  
Respiratory acidosis :  
Acute  $\uparrow$ 10 p CO<sub>2</sub> :  $\uparrow$  1 HCO<sub>3</sub>  
Chronic  $\uparrow$ 10 p CO<sub>2</sub> :  $\uparrow$  3 .5 HCO<sub>3</sub>  
Respiratory alkalosis:  
Acute  $\downarrow$ 10 p CO<sub>2</sub> :  $\downarrow$  2 HCO<sub>3</sub>  
Chronic  $\downarrow$ 10 p CO<sub>2</sub> :  $\downarrow$  5 HCO<sub>3</sub>

Metabolic acidosis:

Expected p CO<sub>2</sub> : ( 1.5 \* HCO<sub>3</sub> ) + 8

If > actual: respiratory acidosis      If < actual : respiratory alkalosis

Metabolic alkalosis :

Expected p CO<sub>2</sub> : change in p CO<sub>2</sub> + 40 = change in HCO<sub>3</sub> \*0.7

( highly variable, and in some cases there may be no or minimal compensation. In chronic metabolic alkalosis, the PaCO<sub>2</sub> should increase by roughly 5 mmHg for every 10 mEq/L increase in serum HCO<sub>3</sub> )

### Approach

1. Acidosis or alkalosis ?

2. Is the overriding disturbance respiratory or metabolic?

Respiratory acidosis:  $\text{PaCO}_2 > 40 \text{ mmHg}$

Metabolic acidosis: serum  $\text{HCO}_3 < 24 \text{ mEq/L}$

3. If a respiratory disturbance is present, is it acute or chronic?

4. If metabolic acidosis is present, is there an increased anion gap?

- can have an anion gap acidosis even with a normal anion gap if hypoalbuminemic (decrease in unmeasured anions).

- anion gap may be increased due to metabolic alkalosis, if  $\text{pH} > 7.5$  more negative charges are exposed on the surface of albumin therefore there is an increase in unmeasured anions.

5. If a metabolic disturbance is present, is the respiratory system compensating adequately?

- there is a linear relationship between  $\text{PaCO}_2$  and serum  $\text{HCO}_3$  in metabolic acidosis

Winter's formula:  $\text{expected PaCO}_2 = [1.5 \times (\text{serum HCO}_3)] + 8$

if  $\text{PaCO}_2$  lower, there is a concomitant primary respiratory alkalosis

if  $\text{PaCO}_2$  higher, there is a concomitant primary respiratory acidosis

- the normal respiratory response is more difficult to predict for a primary metabolic alkalosis.

- appropriate compensation occurs with decreased alveolar ventilation and increased  $\text{PaCO}_2$ , but the  $\text{PaCO}_2$  rarely rises to levels above 50 mmHg

- a subnormal  $\text{PaCO}_2$  clearly indicates a concomitant primary respiratory alkalosis

- if the  $\text{PaCO}_2$  is  $\geq 50 \text{ mmHg}$  this suggests a superimposed primary respiratory acidosis

6. Are other metabolic disturbances present in the patient with an anion-gap metabolic acidosis? calculate the corrected  $\text{HCO}_3 = \text{delta gap} + \text{measured serum HCO}_3$

$\text{delta gap} = \text{calculated anion gap} - 12$  (normal anion gap)

if the corrected  $\text{HCO}_3$  is greater than the expected 24 mEq/L, there is a concomitant primary metabolic alkalosis

if the corrected  $\text{HCO}_3$  is less than the expected 24 mEq/L, there is a mixed disorder with a superimposed non-anion gap metabolic acidosis

### Examples

A 20-year-old man presents with obtundation. Past medical history is unobtainable. Blood pressure is 120/70 without orthostatic change and he is well perfused peripherally. The neurological exam is nonfocal. His laboratory values are :

Na: 138 mEq/L

K: 4.2 mEq/L

HCO<sub>3</sub>: 5 mEq/L

Cl: 104 mEq/L

Creatinine: 1.0 mg/dL

BUN: 14 mg/dL

Ca: 10 mg/dL

Arterial blood gas on room air: PO<sub>2</sub> 96, PCO<sub>2</sub> 15, pH 7.02 Blood glucose: 90 mg/dL

Urinalysis: normal, without blood, protein, or crystals. Which of the following is the most likely acid-base disorder?

- A. Pure normal anion gap metabolic acidosis
- B. Respiratory acidosis
- C. **Pure high anion gap metabolic acidosis**
- D. Combined high anion gap metabolic acidosis and respiratory alkalosis
- E. Combined high anion gap metabolic acidosis and respiratory acidosis

A 50 year old homeless man was brought to ER in stuporous state. BP is 100/50 mmHg , heart rate 120 , respiratory rate 35 and temperature of 40 C. He was found to have left foot cellulitis. His labs are :

Na 150

K 3.5

Cl 107

HCO<sub>3</sub> 10

pH 7.2

pCO<sub>2</sub> 25

Alcohol 40

Osmolality 370

Glucose 50

BUN 40

What is his acid base disorder?

- A. Metabolic acidosis and metabolic alkalosis
- B. **Metabolic acidosis with partial respiratory compensation**
- C. Respiratory acidosis with partial metabolic compensation
- D. Respiratory acidosis
